The influence of oxygen absorbed at high temperatures upon the electrochemical behavior of platinum. T. V. Kalish and R. Kh. Burshteln, *Doklady Akad. Nauk S.S.S.R.* 88, 863-6(1953); cf. *C.A.* 46, 3820d. — The penetration of O into heated Pt was studied by detg. the quantity removed by cathodic polarization. A Pt electrode (20 sq. cm. area) was sealed into a quartz chamber which permitted degassing at 1000°. A known quantity of O ( $12.4-69.4 \times 10^{18}$  mols. of O/sq. cm. apparent area of Pt) was then absorbed at 850, 800, or 750°. Larger amts. (unmeasured) were also absorbed at 0.5 atm. After cooling, degassed electrolyte was added by breaking an ampul. The potential was measured vs. a H electrode until a stable value was reached. A cathodic current of  $2 \times 10^{-4}$  amp. was then applied, and the time for the potential to drop to zero was used as a measure of O removed ( $0.66-6.4 \times 10^{18}$  mols. of O/sq. cm.). The former quantity corresponded to a monolayer. A distinct plateau occurred in 1N H<sub>2</sub>SO<sub>4</sub> at 0.6-0.7 v, but did not occur in 1.42N HCl. Upon interrupting the cathodic polarization in H<sub>2</sub>SO<sub>4</sub> soln., the potential rose fairly rapidly to 0.6-0.7 v. Repeated polarization with periods of interruption was found to remove O gradually arising from deeper layers of the metal. After 4 polarizations,  $2.51 \times 10^{18}$  O<sub>2</sub> mols./sq. cm. were removed after absorbing  $36.5 \times 10^{18}$  mols./sq. cm. at 852°; similarly,  $4.85 \times 10^{18}$  mols./sq. cm. were removed after absorbing  $89.4 \times 10^{18}$  O mols./sq. cm. at the same temp. In several cases, an increase in length of the potential-time plateau was noted after an interruption of several hrs. This was interpreted as a gradual penetration of micropores of the surface by electrolyte. O absorbed at higher temps. required a longer time for removal.

Title : Effect of anion adsorption on the reduction of an  $S_2O_8^{2-}$  ion on a drop cathode

Periodical : Zhur. Fiz. Khim. 28, Ed. 3, 473-489, March 1954

Abstract : It is shown that the reaction of electro-reduction of an  $S_2O_8^{2-}$  ion on a mercury electrode is retarded by the adsorbing anions. The rate of this reaction, at a positive surface charge in relation to the nature of the indifferent electrolyte, decreases gradually. The potential at which the current intensity corresponding to this reaction reaches 0.8 in proportion to the maximum diffusion current is displaced toward the negative side. At a negative surface charge one can observe a certain weakly expressed dependence of the rate of electro-reduction upon the nature of the anions which in this case are oriented in reverse sequence. The effect of adsorption anions leads to the convergence of the potential with the point of the zero-charge. Thirty references; 1 USSR. since 1919. Tables, graphs.

Title : Position of the zero-charge point and its effect on the electro-reduction of a  $S_2O_8^{2-}$  anion on a drop electrode

Periodical : Zhur. Fiz. Khim., 28, Ed. 5, 801 - 805, May 1954

Abstract : Experiments showed that, the beginning of the descent of the polarization curve, during electro-reduction of  $S_2O_8^{2-}$  on a drop electrode consisting of 40% thallium amalgam, is displaced by 0.5 v toward more negative potentials, which corresponds with the position of the zero charge point of thallium amalgam. The retardation of the  $S_2O_8^{2-}$  reduction reaction over a mercury electrode in solutions containing n-octyl alcohol is determined by the absorption of alcohol molecules, the action of which is affected by the negative charges of the surface. Seven USSR references. Graphs.

TITLE:

The Influence of Radiolysis on the Potential of the Nickel  
Electrode in an Alkaline Solution in Dependence on the Com-  
position of the Gas Phase

PERIODICAL:

Doklady Akademii nauk SSSR, 1960, Vol 130, Nr 3, pp 573-576  
(USSR)

ABSTRACT:

The authors found in reference 1 that the potential arising on the action of atomic hydrogen under atmospheric pressure on a nickel electrode in an alkaline solution is by 45 - 60 mv more negative than is the potential of the reversible hydrogen electrode. In the present paper they investigated the behavior of the Ni-electrode under the simultaneous action of atomic hydrogen, atomic oxygen and OH radicals produced by radiolysis. The apparatus which made it possible to carry out the experiments in vacuum or at a certain gas pressure is illustrated in figure 1. The nickel electrodes were reduced at 400° in hydrogen atmosphere and were stored in H until the time of the experiment. 0.68 N NaOH served as alkaline solution. Radiolysis took place by means of an X-ray tube which supplied an energy ✓

of  $6.8 \cdot 10^{16}$  ev/sec per  $\text{cm}^3$  of solution. Figure 2 shows the change with time of the electrode potential in the case of repeated connecting and disconnecting the radiation. The initial potential is by about 250 mv more positive than that of the reversible H-electrode, under the action of radiation it first shifts by about 200 mv in a negative direction, and slowly turns more positive after a few minutes. When radiation is disconnected, a shift occurs in the negative direction. This procedure can be repeated by connecting and disconnecting the radiation, until the electrode is coated with a thick oxide layer. The potential shifts observed are explained by initial adsorption of H and the subsequent action of the oxidizing substances forming in the solution, whose concentration increases with the duration of the irradiation. The reaction course in the solution, the formation and the decomposition of  $\text{H}_2\text{O}_2$  are still to be investigated. The curves drawn in the presence of neon (6 - 10 torr) agree with the curves drawn in

the absence of gas. Figure 3 shows the behavior of the nickel electrode in the presence of gaseous hydrogen (60 torr, 6 torr) and H + He (1 + 6 torr). In this case, only slight changes of potential occur with connecting and disconnecting of the radiation; this potential almost coincides with the one of reversible H-electrode in the case of H + He. The still present low potential fluctuations are explained by thermal effects and redox processes. The authors mention Ta. I. Zalkind and V. I. Veselovskiy (Refs 3,4), and N. A. Shumovskaya and R. Kh. Burshteyn (Ref 5). They thank Academician A. N. Frumkin and P. I. Dolin for discussing the experimental data. There are 3 figures and 6 references, 5 of which are Soviet.

TOPIC TAGS: rimmed steel, alloy composition, molten metal, slag, metallurgic process, metal analysis

ABSTRACT: The influence of the composition of the steel before tapping on the quality of the steel is discussed; the relative importance of the contents of oxygen, manganese and carbon are described. The relationship between the release of carbon monoxide and the contents of carbon and of oxygen is reviewed. A method for the calculation of the content of theoretical oxygen in the steel is described; the determination of the amount of deoxidant required is discussed. A method for checking the results of deoxidation by the analysis of a slag sample is described. Orig. art. has: 8 figures and 1 table. [Based on authors' Eng. abst.] [JPRS: 34,519]

TITLE: Using phase transitions to improve the thermostatic control of instruments

SOURCE: Moscow. Vsesoyuznyy nauchno-issledovatel'skiy institut geofizicheskikh metodov razvedki. Prikladnaya geofizika, no. 45, 1965, 145-156

TOPIC TAGS: phase transition, thermostat, gravimeter, gallium base alloy, ice, eutectic mixture

ABSTRACT: The authors consider methods for improving the accuracy of thermostatic control when using delicate instruments in physical experiments such as measuring the force of gravity for geological prospecting purposes. The thermostating action of low-melting materials during phase transitions from the solid to the liquid state and back is considered as a possibility for practical use in highly accurate gravimetric measurements. The opposition to changes in temperature in this case is due to the latent energy of the phase transitions (melting--solidification) of the fusible materials. A thermostat based on the two-phase principle with ice as the fusible material was used for a quartz astatized gravimeter in 1954 at the Gravimetric Institute of the All-Union Scientific Research Institute of Geophysics. The instrument was found to be sensi-

Card 1/2

L 29710-66

ACC NR: AT6015408

2

tive to mechanical shock and caused sweating of some of the gravimeter glasses. Experimental thermostats using gallium, gallium-based eutectic alloys and hydrocarbons are described. Out of a total of 87 alloys which were studied, two were found to have promise as materials for two-phase thermostats: Ga-Zn (95% Ga, 5% Zn, melting point 25°) alloyed with lithium (2-3% Li) and bismuth (0.05-0.1% Bi), and Ga-Sn (92% Ga, 8% Sn, melting point 20°) alloyed with bismuth (0.5-1% Bi) and lithium (0.5-1% Li). The purity of the initial components, accuracy in maintaining the eutectic ratio and absence of harmful impurities are extremely important. The thermostat was made in the form of a double-walled polyethylene housing placed over the gravimeter case and put into a Dewar flask together with the gravimeter. The space between the walls of the thermostat was filled with the fusible material. Tests of the thermostat with a gallium-tin working alloy showed satisfactory resistance to thermal shock at the required temperature (20°). Among the hydrocarbons tested, the most satisfactory was n-heptadecane ( $C_{17}H_{36}$ ) with a melting point of 22°. Field tests of a gravimeter using a two-phase thermostat based on this material showed a zero drift of 1.3  $\mu$ gal/hr which is 1/10-1/20 of the drift for the same gravimeter without compensation. TITLE: Standard heat capacities, entropies, and enthalpies of silicon, and of chromium and its silicides

SOURCE: Zhurnal fizicheskoy khimii, v. 39, no. 12, 1965, 2999-3001

TOPIC TAGS: heat capacity, entropy, enthalpy, silicon, chromium compound

ABSTRACT: The article reports a study of the temperature dependence of the heat capacities of silicon and of chromium and its silicides in the temperature interval from approximately 54 to 300°K. The alloys for the investigation were prepared from monocrystalline silicon (> 99.999% Si) and electrolytic chromium (~ 99.98% Cr). Corresponding amounts of the components were melted in a type MVP-3M induction furnace in an argon atmosphere. A homogenizing anneal of the billets was carried out at 1600°K. By this method, the following stoichiometric silicides were obtained: Cr<sub>3</sub>Si, Cr<sub>5</sub>Si<sub>3</sub>, CrSi, and CrSi<sub>2</sub>. A large table gives the

Card 1/2

UDC: 541.11

L 36958-66

ACC NR: AP6014896

values found for the heat capacities of the above substances at different temperatures. From the heat capacity measurements, calculations were made of the characteristic temperatures  $\Theta_D$ , the standard entropies  $S_{298.5}^0$ , and the enthalpies  $\Delta H_{298.5}^0$ . The additive rule is not valid for calculation of the heat capacities of the chromium silicides; its application for the calculation of the standard entropies gives an error not exceeding 4-5%. Orig. art. has: 1 figure and 2 tables.

TITLE: The Problem of the Genesis of Spilite-Keratophyre (K voprosu ob usloviyakh obrazovaniya porod spilito-keratofirovoy formatsii)

PERIODICAL: Doklady Akademii nauk SSSR, 1968, Vol 122, Nr 5, pp 902-904 (USSR)

ABSTRACT: The spilite-keratophyre formation (the zelenokamennaya green-stone formation) is typical of geosynclines. Such rocks usually originate in the beginning of the geosynclinal cycle (Ref 2). According to present ideas (Ref 1), the spilitic formations, although occurring with differing acidities, are built over a long period of time under submarine conditions. It is just these conditions and not the original compositions that are held responsible for the peculiar end-composition (markedly differing from the usual calc-alkali series) of the spilite lavas. The paleogeography of Sakhalin during the Tertiary was often favorable for the formation of spilite-keratophyre (Early and Middle Miocene, Ref 3, Late Neogene, Early Pliocene). An analysis of fauna remains in these formations allows not only

DOI, 20-122-1-45/56

the exact determination of the time of volcanic activity, but also the determination of the paleoenvironment, especially the depth of the water in which single eruptions took place. Mrs. T. G. Kalishevich on the basis of the fossil associations and the lithology concluded that the pillow lavas and ball lavas (of the Vyazovka River and Cape Staritskogo) erupted at a depth of approximately 20-30 m under normal conditions of salinity and gas exchange. On the other hand the analogous lavas on the north point of Cape Amanon erupted in the littoral zone, at depths of less than 15-20 m. Due to the rapid cooling the lavas are quite glassy with a microporphyrific texture. Although the extrusion under the water has produced a special texture and also to some extent influenced the mineral composition, the plagioclase is in no way albitized - the particular characteristic of spilite-keratophyre. This study has shown that submarine eruption alone, at least up to depths of 100 m, is not enough to produce spilite lavas. There are 1 table and 6 references, 4 of which are Soviet.

**Leucophyll and protochlorophyll.** T. N. Golubev and S. V. Kalinovich. *Trudy Inst. Fiziol. Rastenií im. A. A. Timiryazeva*, 4, No. 2, 100-6 (1945).—A review with many references on the natural formation of chlorophyll is presented. A theory of formation is formulated thus: the 1st step is formation of pyrrole compds. having a H in the  $\alpha$ -position, which then condense with  $\text{CH}_2\text{O}$  to yield leucophyll, which by oxidation gives tetrahydroxyprotophyrinogen, which by a loss of  $\text{H}_2\text{O}$  may give tetrapyrrolineporphyrin which is reduced, in several steps, to protochlorophyll or chlorophyll. Although it was not possible to isolate leucophyll from the exptl. plant sprouts, the reduction of protochlorophyll to the leuco deriv. was demonstrated; the latter oxidizes to a substance whose spectrum is comparable to that of protochlorophyll. The inner skins of the pumpkin seeds were rapidly extd. with pyridine and the ext. aliquot was dild. with  $\text{EtOH}$ . This was treated with aq.  $\text{AcOH}$  and  $\text{Zn}$  dust in  $\text{N}_2$  atm. for 2 hrs. at room temp. The pale yellow soln. could be kept without change under pettiolatum for 2 months. Bubbling with  $\text{O}$  reoxidizes the material in 1 hr. at  $80^\circ$ , in 2 hrs. at  $50^\circ$ , while standing in the air at  $15^\circ$  required 32 hrs. for reoxidation. The oxidized soln. on passage through sucrose moistened with benzene gave 3 absorption zones: a narrow dark one (where concn. of a component with abs. bands at 6282-6175, 6010-5906, 5817-5649, 5589-5470, and 5340-5109  $\text{\AA}$ . took place), a middle green zone (where concn. of component with abs. bands at 6325-6197, 6057-5838, 5545-5302, 5294-5111 and 5111-5233  $\text{\AA}$ . took place) and a yellow carotenoid zone. ABSTRACT: On the strength of the Sinegorsk-Zagorsk exposure several authors (References 1-3,9,11) came to a conclusion concerning the discordant stratification of the Naybutinskaya (Nizhneduyskaya) suite as marine sediments of Upper Cretaceous (Senonian stage) though they did not observe the contact of the Cretaceous and Tertiary sediments. Kurosava (Reference 5) said that there was no clear boundary of this kind. On the strength of newest investigations a detailed scheme of the exposure in question was determined. The author is of the same opinion, as all previous researchers, that there is no interval in the mass which formerly had been classified to the Senonian stage. He found for the

Title : Critical analysis of the A. J. Quick hypothesis regarding the biochemical role of blood plasma in the process of blood coagulation

Periodical : Dokl. AN SSSR, 96, Ed. 5, 1029 - 1031, June 1954

Abstract : A critical analysis is presented on the A. J. Quick hypothesis regarding blood plasma and blood coagulation. The experimental results obtained by the authors do not confirm the Quick hypothesis but give basis to the belief that blood plasma is the sources of prothrombokinesis and plasma contains thrombotropine as its activator. The substance in the blood plasma does not activate prothrombokinesis of the tissue but becomes itself activated by coming in contact with the plasma agent - thrombotropine. Twelve references. 2  
Change of the thromboplastic activity of blood and strength of the capillaries after splenectomy. B. A. Kudryashov, T. M. Kalishevskaya, and V. B. Pastorova (M. V. Lomonosov State Univ., Moscow). Doklady Akad. Nauk S.S.S.R. 107, 185-7(1958).—Complete removal of the spleen from white rats leads to a rapid and great drop in the thromboplastic activity of blood. After 2 weeks there begins a restoration of this function which is complete in some 4 weeks. Along with the drop in thromboplastic activity there is a parallel drop in the strength of the capillaries, whose restoration occurs somewhat earlier, however.

"Species Specificity of Prothrombokinase of Blood Platelets and of Thrombotropin," by T. M. Kalishevskaya, Moscow State University imeni M. V. Lomonosov, Doklady Akademii Nauk SSSR, Vol 112, No 3, 1957, p 477-480

The purpose of the investigation was to study species specificity of prothrombokinase of blood platelets.

Data obtained on the study of species characteristics in the activation of prothrombokinase by thrombotropin show that there are substantial differences between two species of thromboplastic substance. Tissue prothrombokinase (brain) has marked species specificity, indicated by lack of activation of brain prothrombokinase by certain species of plasma thrombotropin, whereas the prothrombokinase of the blood platelets does not exhibit so marked a species specificity.

Thrombokinase of the blood platelets, as also the thrombokinase of the human brain and of corresponding animal species, lacks species specificity in the sense that it is capable of hastening the transformation of prothrombin into thrombin in the plasma of various species. (U)

**PERIODICAL** Doklady Akademii Nauk SSSR 1957 Vol 114 Nr 5, pp 1128-1131 (U.S.S.R.)

**ABSTRACT** The authors showed already previously that a complete splenectomy in animals leads to an abrupt thromboplastic activity of the blood. At the same time a certain loss of solidity of the capillaries is observed. The present investigation is dedicated to the study of the immediate causes of the catastrophic reduction of the mentioned blood activity. This activity depends on the amount and quality of prothrombokinase in the blood platelets (of factor 3 of the blood platelets) and on the level of thrombotropine in the plasma. Therefore, when tests were resumed, chief attention was concentrated on the study of the number of blood platelets and the prothrombokinase "charge" contained in them. The concentration of this latter enzyme in the plasma at different stages of the ex-

CARD 1/4

Blood Prothrombokinese and Thrombotropine Deficiency in Splenectomised Rats.

under control of vitamin K. In operated animals which received large doses of 2-methyl -3,4-naphthoquinone and in others which received small doses of synkavit, the thrombotropine concentration was restored after 24 hours. It was found to decrease further by 15 %. In spite of this restoration the former low thromboplastic blood activity was conserved in the rats. This indicates that the noticed decrease in concentration to 40 % is not the only and main cause of the catastrophic decrease in blood activity. Therefore the prothrombokinese of blood platelets as the second agent on which the formation of blood thrombokinese depends was studied. On the 7th to 8th day after the full operation the number of erythrocytes in the blood is considerably reduced: the number of blood platelets rises sharply. It seems that there occurs a certain absolute increase in platelets at this time. The results indicate that the prothrombokinese deficiency (of factor 3 of the blood platelets) occurring in splenectomised

CARD 3/4

Blood Prothrombokinase and Thrombotropine Deficiency in Splenectomised Rats.

rats is due to an infection agent (bartonellosis). Thus the insufficiency of blood platelets with regard to factor 3 may be a consequence of infectious toxicoses. This phenomenon can be removed by antiinfectious agents.

TITLE: The Flow Structure and Aerodynamic Characteristics of a Cyclone Chamber During Combustion (Struktura potoka i aerodinamicheskiye kharakteristiki tsiklonnoy kamery pri goreнии)

PERIODICAL: Teploenergetika, 1958, No 2, pp 27 - 33 (USSR)

ABSTRACT: A comprehensive study of the cyclone process of combustion of solid fuel that is being made by the Moscow Division of the Central Boiler Turbine Institute (MO TsKTI) and the "Boiler Installations" Faculty of the Moscow Higher Technical College imeni Bauman. The programme includes experiments on the aerodynamics of a cyclone furnace during combustion. One stage of this work was investigation of the aerodynamics of flow in a cyclone chamber when gas oil was being burned. The tests were carried out on the test cyclone chamber described in an article in Teploenergetika, 1958, no.1. The cyclone diameter is 650 mm and its length 680 mm. Other dimensions and characteristics are given. The experimental work showed that the nature of the changes in the rotational velocity across the radius of the chamber is the same when fuel is burned as with cold air (see Fig.1a). However, the relative rotational speeds are higher during combustion. As shown in Fig.2, on transition to combustion there is approximation to the rotational component of the dynamic

Card1/5

96-58-2-5/23

The Flow Structure and Aerodynamic Characteristics of a Cyclone (Cont.)

head.

The qualitative distribution of axial velocities in the chamber is the same during combustion as on cold air. Nor is there any essential difference in the magnitudes of the axial velocities in the two cases if mass axial velocities are compared as in Fig.3. The relative values of the total and static pressures are higher during combustion than with cold air. The constructional changes that were made when changing from cold air to fuel-burning have not altered the nature of the main aerodynamic changes of the cyclone flow that result from combustion. In all the tests, the relative total head and, therefore, the resistance factor are higher during combustion than when blowing.

Determination of the temperature distribution in the chamber when burning gas oil showed that even quite close to the secondary air entry the gas temperature is 3 - 4 times higher than the initial air temperature; also, its value rises rapidly to approach the mean temperature at the outlet from the chamber. The temperature distribution in the chamber is relatively uniform and some reduction in temperature is observed only in the peripheral part of the flow. During combustion, there is no qualitative change in the structure of the flow, nor in the nature of pressure and velocity distribution in the chamber.

Card2/5

96-58-7-5/23

The flow structure and Aerodynamic Characteristics of a Cyclone (Cont.)

However, the quantitative characteristics during combustion differ greatly from those obtaining with isothermal flow. This is due to great increase in the mean temperature level. An analysis is given of the possibility of co-relating the 'hot' and 'cold' aerodynamics. Special attention is paid to the influence of the mean temperature of the flow and, as a first approximation, temperature irregularities in the volume of the chamber are neglected. Expressions are derived for the rotary and axial speeds at the inlet to the chamber with and without combustion. The effect of combustion on the static and total pressures is considered.

An investigation of the aerodynamic structure of the flow when burning pulverised gas-coal was also made on the same rig. The fuel and primary air were delivered axially. The tests were made with a fuel consumption of 320 kg/hour, a hot-air temperature of 320 °C, a secondary air flow of 2 020 m<sup>3</sup>/hour and a primary air speed of 163 m/sec, the primary air being 20% of the total. The test results were used to construct graphs of the changes in tangential and axial velocities and also of the total and static pressures at various cross-sections of the chamber. Comparison of the results of these tests with data obtained with cold air and when burning gas oil showed that the

Card 3/5

96-58-2-5/23

The Flow Structure and Aerodynamic Characteristics of a Cyclone(Cont.)

nature of the changes in the rotational velocities at different cross-sections of the chamber is the same as when burning gas oil, as is shown in Fig.4A. The velocities in the peripheral part of the head sections are somewhat higher. The distribution of the rotational components of the dynamic heads is similar when burning coal or oil and when blowing cold air. However, their values are lower than when burning oil because the presence of particles of fuel and slag in the gas flow reduces the swirling (see Fig.5).

The effects observed when burning gas oil and solid fuel are then compared in some detail. The observations on the influence of combustion on the aerodynamics of a cyclone chamber are not complete and the work is continuing. However, it can be said that the combustion of coal in the chamber does not lead to any qualitative change in the aerodynamics of flow. The quantitative difference between burning coal and oil consists in a reduction of the rotational velocities and of the static and total heads. The main properties and the velocity and pressure relationships of the cyclone chamber are the same when blowing cold air during combustion.

The results gave some idea of the difference between flows in Card4/5<sup>a</sup> model and in an actual furnace chamber, and the differences

96-58-2-5/23

The Flow Structure and Aerodynamic Characteristics of a Cyclone

are explained. The various flow equations are analysed. The relationship established between the aerodynamic characteristics of the cyclone chamber and its operational conditions and geometrical dimensions makes the results obtained on the rig valid for industrial furnaces, provided the chambers are similar. Comparisons between the coefficients of conservation of velocity obtained on a chamber with smooth walls with single-phase and two-phase flows and between the coefficients of conservation of velocity when burning gas oil and gas coal in the rig chamber show that in both cases the presence of two phases leads to approximately the same reduction in the coefficient of conservation of velocity. This means that a considerable reduction in the swirl, caused by increased frictional losses on the rough walls and by combustion, does not cause a noticeable change in the effect that suspended particles have on the flow characteristics.

ETITLE: Investigation of the aerodynamic structure of cyclone burners during combustion of solid fuel

SOURCE: Teploenergetika, no. 8, 1966, 72-75

TOPIC TAGS: combustion, solid fuel, flow structure, aerodynamic characteristic, turbulent flow

ABSTRACT: The authors study flow motion in axial and tangential cyclone burners 620 mm in diameter with  $L/D$  ratios of 1.25 and 1.1 respectively and an outlet nozzle diameter of 0.44  $D$ . Helical input of secondary air is done through three nozzles 85, 218 and 105 mm wide in the axial chamber, and through four nozzles 130, 130, 130 and 115 mm wide in the tangential chamber. Water-cooled pneumometric probes were used for taking the velocity fields in the cyclone. The measurements were made during combustion of low-ash concentrates. Comparison measurements were made during combustion of diesel fuel and cold blow-through. Experiments under characteristic optimum conditions for the axial burner showed a considerable reduction in the coefficient of

TITLE: Some results of a study of nonstationary turbulent motion

SOURCE: Teploenergetika, no. 1, 1967, 69-72

TOPIC TAGS: turbulent flow, nonsteady flow, flow stream, perturbation, laminar flow, boundary layer, gas dynamics, Reynolds number

ABSTRACT: The results of a theoretical and experimental study of nonstationary turbulent flow are presented. It is assumed that if flow can be considered quasi-stationary in the boundary region, it is quasi-stationary in the entire flow region. The stream can be considered quasi-stationary if

$$\frac{\delta_1^2}{\nu w} \frac{\partial w}{\partial t} < 1,$$

where  $\nu$  is the kinematic modulus of viscosity;  $w$  - the average flow velocity; and  $\delta_1$  - the thickness of the viscous sublayer. Theoretical analysis of the hydrodynamic equations shows that, for a nonstationary turbulent stream, the effects of nonstationarity can be ignored when

$$K = \frac{\nu}{w \delta_1} \frac{\partial w}{\partial t} < 4 \cdot 10^{-4},$$

Card 1/2

UDC: 533.517.4.001.5

ACC NR: AP7003341

where K is the nonstationarity number. The experimental results of measurements of the velocity fields, tube drag, and tangential stresses on the wall in a turbulent air stream confirm the theoretical result. A method for complete description of the dynamic properties of pressure probes is proposed. Orig. art. has: 10 formulas and 6 graphs.

TITLE: Revision Principles for Standards of Piston Steam Pumps  
(Printsipy peresmotra standartov na parovyye porshnevyye nasosy)

PERIODICAL: Standartizatsiya, 1957, # 4, pp 21-25 (USSR)

ABSTRACT: The old standards, GOCT 579-41, 580-41, 582-41, 2834-45, 3619-47, covering 100 models of steam pumps and about 30 of motor-driven pumps are under revision. The author cites a few examples of inadequacies in the old.

The new GOCT 8336-57 "Pumps, Piston, Steam, Horizontal Type, Basic Parameters and Dimensions" will be put into effect on 1 January 1958, replacing the GOCT 579-41, 580-41 and 2834-45. This is for water pumps, dark petroleum products of up to 110° BY viscosity and 100°C, and other like fluids, with steam work pressure of 16 kg/cm<sup>2</sup>. The pumps are direct action, two-cylinder, 4 stage. The number of models is reduced from 100 to 30. The accepted pressure gradations and feed limits are given in a chart (table 1). The series is built on feed stages

Pewne problemy brzegowe dynamicznej teorii sprzystosci i cial niesprzystych (Certain Boundary Problems of the Dynamic Theory of Elasticity and Dynamics of Nonelastic Bodies) Warszawa, Wojskowa Akademia Techniczna, 1957. 305 p. Number of copies printed not given.

Eds.: Marian Dacko, and Henryk Sejneński.

PURPOSE: This dissertation for the degree of Doctor of Technical Sciences may be of interest to engineers and scientists working in the field of advanced theory of elasticity.

COVERAGE: The object of this paper is to present in a uniform manner general solutions to dynamical boundary problems by using dynamical displacement and stress functions. Homogeneous and nonhomogeneous isotropic and anisotropic elastic bodies are considered together with nonhomogeneous anelastic bodies showing anisotropic relaxation characteristics. Arbitrary nonstationary
